#### DETAILED DESCRIPTION OF THE INVENTION

The present invention is based upon the discovery of heretofore unknown compounds that surprisingly and unexpectedly, are modulators of the activity of peroxisome proliferator-activated receptors (PPARs). PPARs are transcription factors which can be activated by ligands and belong to the

20

class of nuclear hormone receptors. There are three PPAR isoforms, PPARalpha, PPARgamma and PPARdelta, which are encoded by different genes (Peroxisome proliferator-activated receptor (PPAR): structure, mechanisms of activation and diverse functions: Motojima K, Cell Struct Funct. 1993 Oct; 18(5): 267-77).

25

Two variants of PPARgamma exist, PPARgamma<sub>1</sub> and gamma<sub>2</sub>, which are the result of alternative use of promoters and differential mRNA splicing (Vidal-Puig et al. J. Clin. Invest., 97:2553-2561, 1996). Different PPARs have different tissue distribution and modulate different physiological

30

functions. The PPARs play a key role in various aspects of the regulation of a large number of genes, the products of which genes are directly or indirectly crucially involved in lipid and carbohydrate metabolism. Thus, for example, PPARalpha receptors play an important part in the regulation of fatty acid catabolism or lipoprotein metabolism in the liver, while

35

PPARgamma is crucially involved for example in regulating adipose cell

differentiation. In addition, however, PPARs are also involved in the regulation of many other physiological processes, including those which are not directly connected with carbohydrate or lipid metabolism. The activity of different PPARs can be modulated by various fatty acids, fatty acid derivatives and synthetic compounds to varying extents. As used herein, "aryl" refers an aromatic carbocyclic mono- or bicyclic ring system which comprises 6 to 10 atoms in the ring or rings.

30

As used herein, "heteroaryl" refers to a mono- or bicyclic aromatic ring system having 4 to 11 ring members, in which at least one atom in the ring system is a heteroatom from the series N, O and S.

- 10 Pharmaceutically acceptable salts are, because their solubility in water is greater than that of the initial or basic compounds, particularly suitable for medical applications. These salts must have a pharmaceutically acceptable anion or cation. Suitable pharmaceutically acceptable acid addition salts of

Suitable pharmaceutically acceptable basic salts are ammonium salts, alkali metal salts (such as sodium and potassium salts), alkaline earth metal salts (such as magnesium and calcium salts), and salts of trometamol (2-amino-2-hydroxymethyl-1,3-propanediol), diethanolamine, lysine or ethylenediamine.
- 25 Salts with a pharmaceutically unacceptable anion such as, for example, trifluoroacetate likewise belong within the framework of the invention as useful intermediates for the preparation or purification of pharmaceutically acceptable salts and/or for use in nontherapeutic, for example in vitro,  
30 applications.

- 30 As used herein, the term "physiologically functional derivative" refers to any physiologically tolerated derivative of a compound of the formula I of the invention, for example an ester, which on administration to a mammal such as, for example, a human is able to form (directly or indirectly) a compound  
35 of the formula I or an active metabolite thereof.

Physiologically functional derivatives also include prodrugs of a compound of the present invention, as described, for example, in H. Okada et al., Chem. Pharm. Bull. 1994, 42, 57-61. Such prodrugs can be metabolized *in*

#### Formulations

- 15 As explained above, the present invention extends to a pharmaceutical composition comprising a compound of the present invention and a pharmaceutically acceptable carrier. The phrase "pharmaceutically acceptable" refers to molecular entities and compositions that are physiologically tolerable and do not typically produce an allergic or similar
- 20 untoward reaction, such as gastric upset, dizziness and the like, when administered to a human. In particular, as used herein, the term "pharmaceutically acceptable" means approved by a regulatory agency of the Federal or a state government or listed in the U.S. Pharmacopeia or other generally recognized pharmacopeia for use in animals, and more particularly
- 25 in humans. The term "carrier" refers to a diluent, adjuvant, excipient, or vehicle with which the compound is administered. Such pharmaceutical carriers can be sterile liquids, such as water and oils, including those of petroleum, animal, vegetable or synthetic origin, such as peanut oil, soybean oil, mineral oil, sesame oil and the like. Water or aqueous solution saline
- 30 solutions and aqueous dextrose and glycerol solutions are preferably employed as carriers, particularly for injectable solutions. Suitable pharmaceutical carriers are described in "Remington's Pharmaceutical Sciences" by E.W. Martin.
- 35 The carrier may be a solid or a liquid or both and is preferably formulated with the compound as a single dose, for example as a tablet, which may

contain from 0.05% to 95% by weight of the active ingredient. Other pharmaceutically active substances may likewise be present, including other compounds of formula I. The pharmaceutical compositions of the invention can be produced by one of the known pharmaceutical methods, which essentially consist of mixing the ingredients with pharmacologically acceptable carriers and/or excipients.

Pharmaceutical compositions of the invention are those suitable for oral, rectal, topical, peroral (for example sublingual) and parenteral (for example subcutaneous, intramuscular, intradermal or intravenous) administration, although the most suitable mode of administration depends in each individual case on the nature and severity of the condition to be treated and on the nature of the compound of formula I used in each case. Coated formulations and coated slow-release formulations also belong within the framework of the invention. Preference is given to acid- and gastric juice-resistant formulations. Suitable coatings resistant to gastric juice comprise cellulose acetate phthalate, polyvinyl acetate phthalate, hydroxypropylmethylcellulose phthalate and anionic polymers of methacrylic acid and methyl methacrylate.

Suitable pharmaceutical preparations for oral administration may be in the form of separate units such as, for example, capsules, cachets, suckable tablets or tablets, each of which contain a defined amount of the compound of formula I; as powders or granules, as solution or suspension in an aqueous or nonaqueous liquid; or as an oil-in-water or water-in-oil emulsion. These compositions may, as already mentioned, be prepared by any suitable pharmaceutical method which includes a step in which the active ingredient and the carrier (which may consist of one or more additional ingredients) are brought into contact. The compositions are generally produced by uniform and homogeneous mixing of the active ingredient with a liquid and/or finely divided solid carrier, after which the product is shaped if necessary. Thus, for example, a tablet can be produced by compressing or molding a powder or granules of the compound, where appropriate with one or more additional ingredients.

Compressed tablets can be produced by tableting the compound in free-flowing form such as, for example, a powder or granules, where appropriate mixed with a binder, glidant, inert diluent and/or one (or more) surface-active/dispersing agent(s) in a suitable machine. Molded tablets

- 5 can be produced by molding the compound, which is in powder form and is moistened with an inert liquid diluent, in a suitable machine.

- Pharmaceutical compositions which are suitable for peroral (sublingual) administration comprise suckable tablets which contain a compound of formula I with a flavoring, normally sucrose and gum arabic or tragacanth, and pastilles which comprise the compound in an inert base such as gelatin and glycerol or sucrose and gum arabic.
- 10

- Pharmaceutical compositions suitable for parenteral administration comprise preferably sterile aqueous preparations of a compound of formula I, which are preferably isotonic with the blood of the intended recipient. These preparations are preferably administered intravenously, although administration may also take place by subcutaneous, intramuscular or intradermal injection. These preparations can preferably be produced by mixing the compound with water and making the resulting solution sterile and isotonic with blood. Injectable compositions of the invention generally contain from 0.1 to 5% by weight of the active compound.
- 15
- 20

- Pharmaceutical compositions suitable for rectal administration are preferably in the form of single-dose suppositories. These can be produced by mixing a compound of the formula I with one or more conventional solid carriers, for example cocoa butter, and shaping the resulting mixture.
- 25

- Pharmaceutical compositions suitable for topical use on the skin are preferably in the form of ointment, cream, lotion, paste, spray, aerosol or oil. Carriers which can be used are petrolatum, lanolin, polyethylene glycols, alcohols and combinations of two or more of these substances. The active ingredient is generally present in a concentration of from 0.1 to 15% by weight of the composition, for example from 0.5 to 2%.
- 30

Transdermal administration is also possible. Pharmaceutical compositions suitable for transdermal uses can be in the form of single plasters which are suitable for long-term close contact with the patient's epidermis. Such  
5 plasters suitably contain the active ingredient in an aqueous solution which is buffered where appropriate, dissolved and/or dispersed in an adhesive or dispersed in a polymer. A suitable active ingredient concentration is about 1% to 35%, preferably about 3% to 15%. A particular possibility is for the active ingredient to be released by electrotransport or iontophoresis as  
10 described, for example, in *Pharmaceutical Research*, 2(6): 318 (1986).

The compounds of the formula I are distinguished by favorable effects on metabolic disorders. They beneficially influence lipid and sugar metabolism, in particular they lower the triglyceride level and are suitable for the  
15 prevention and treatment of type II diabetes and arteriosclerosis and the diverse sequelae thereof.

#### Methods For Treating And/Or Preventing Disease Or Condition

20 This invention relates further to the use of compounds of the formula I and their pharmaceutical compositions as PPAR ligands. The PPAR ligands of the invention are suitable as modulators of PPAR activity. As explained above, PPARs are transcription factors which can be activated by ligands and belong to the class of nuclear hormone receptors. There are three  
25 PPAR isoforms, PPARalpha, PPARgamma and PPARdelta, which are encoded by different genes (Peroxisome proliferator-activated receptor (PPAR): structure, mechanisms of activation and diverse functions: Motojima K, *Cell Struct Funct.* 1993 Oct; 18(5): 267-77).

30 Two variants of PPARgamma exist, PPARgamma<sub>1</sub> and gamma<sub>2</sub>, which are the result of alternative use of promoters and differential mRNA splicing (Vidal-Puig et al. *J. Clin. Invest.*, 97:2553-2561, 1996). Different PPARs have different tissue distribution and modulate different physiological functions. The PPARs play a key role in various aspects of the regulation of  
35 a large number of genes, the products of which genes are directly or

indirectly crucially involved in lipid and carbohydrate metabolism. Thus, for example, PPARalpha receptors play an important part in the regulation of fatty acid catabolism or lipoprotein metabolism in the liver, while PPARgamma is crucially involved for example in regulating adipose cell differentiation. In addition, however, PPARs are also involved in the regulation of many other physiological processes, including those which are not directly connected with carbohydrate or lipid metabolism. The activity of different PPARs can be modulated by various fatty acids, fatty acid derivatives and synthetic compounds to varying extents. For relevant reviews about functions, physiological effect and pathophysiology, see: Joel Berger et al., Annu. Rev. Med. 2002, 53, 409 – 435; Timothy Wilson et al. J. Med. Chem., 2000, Vol. 43, No. 4, 527-550; Steven Kliewer et al., Recent Prog Horm Res. 2001; 56: 239-63.

The present invention relates to compounds of the formula I suitable for modulating the activity of PPARs, especially the activity of PPARalpha and PPARgamma. Depending on the modulation profile, the compounds of the formula I are suitable for the treatment, control and prophylaxis of the indications described hereinafter, and for a number of other pharmaceutical applications connected thereto (see, for example, Joel Berger et al., Annu. Rev. Med. 2002, 53, 409 – 435; Timothy Wilson et al. J. Med. Chem., 2000, Vol. 43, No. 4, 527-550; Steven Kliewer et al., Recent Prog Horm Res. 2001; 56: 239-63; Jean-Charles Fruchart, Bart Staels and Patrick Duriez: PPARs, Metabolic Disease and Arteriosclerosis, Pharmacological Research, Vol. 44, No. 5, 345-52; 2001; Sander Kersten, Beatrice Desvergne & Walter Wahli: Roles of PPARs in health and disease, NATURE, VOL 405, 25 MAY 2000; 421-4; Ines Pineda Torra, Giulia Chinetti, Caroline Duval, Jean-Charles Fruchart and Bart Staels: Peroxisome proliferator-activated receptors: from transcriptional control to clinical practice, Curr Opin Lipidol 12: 2001, 245-254).

Thus, the present invention extends to a method of treating and/or preventing a disease or condition in a patient, comprising administering a therapeutically effective amount of a compound of formula I to the patient.

As used herein, the phrase "therapeutically effective amount" is used herein to mean an amount sufficient to cause an improvement in a clinically significant condition in the patient or even prevent a disease, disorder or condition in a patient. The amount of a compound of formula I necessary

5 to achieve the desired biological effect depends on a number of factors, for example the specific compound chosen, the intended use, the mode of administration and the clinical condition of the patient. The daily dose is generally in the range from 0.001 mg to 100 mg (typically from 0.01 mg to 50 mg) per day and per kilogram of bodyweight, for example  
10 0.1-10 mg/kg/day. An intravenous dose may be, for example, in the range from 0.001 mg to 1.0 mg/kg, which can suitably be administered as infusion of 10 ng to 100 ng per kilogram and per minute. Suitable infusion solutions for these purposes may contain, for example, from 0.1 ng to 10 mg, typically from 1 ng to 10 mg, per milliliter. Single doses may contain, for  
15 example, from 1 mg to 10 g of the active ingredient. Thus, ampules for injections may contain, for example, from 1 mg to 100 mg, and single-dose formulations which can be administered orally, such as, for example, capsules or tablets, may contain, for example, from 0.05 to 1000 mg, typically from 0.5 to 600 mg. For the therapy of a disease or condition set  
20 forth below, a compound of formula I may be used as the compound itself, but they are preferably in the form of a pharmaceutical composition with a pharmaceutically acceptable carrier.

## Assays

### 5 (A) Determination of EC50 values of PPAR agonists in the cellular PPARalpha assay

#### Principle

10 The potency of substances that bind to human PPAR $\alpha$  and activate in an agonistic manner is analyzed using a stably transfected HEK cell line (HEK= human embryo kidney) which is referred to here as PPARalpha reporter cell line. It contains two genetic elements, a luciferase reporter element (p $\Delta$ M-GAL4-Luc-Zeo) and a PPARalpha fusion protein (GR-GAL4-humanPPAR $\alpha$ -LBD) that mediates expression of the luciferase reporter  
15 element depending on a PPARalpha ligand. The stably and constitutively expressed fusion protein GR-GAL4-humanPPARalpha-LBD binds in the cell nucleus of the PPARalpha reporter cell line via the GAL4 protein portion to the GAL4 DNA binding motifs 5'-upstream of the luciferase reporter element which is integrated in the genome of the cell line. There is  
20 only little expression of the luciferase reporter gene without addition of a PPARalpha ligand if fatty acid-depleted fetal calf serum (cs-FCS) is used in the assay. PPAR $\alpha$  ligands bind and activate the PPAR $\alpha$  fusion protein and thereby bring about expression of the luciferase reporter gene. The luciferase which is formed can be detected by means of  
25 chemiluminescence via an appropriate substrate.

#### Construction of the cell line

30 The PPARalpha reporter cell line was prepared in 2 stages. Firstly, the luciferase reporter element was constructed and stably transfected into HEK cells. For this purpose, five binding sites of the yeast transcription factor GAL4 (each 5'-CGGAGTACTGTCCTCCGAG-3' (SEQ ID NO:1)) were cloned in 5'-upstream of a 68 bp-long minimal MMTV promoter (Genbank Accession # V01175). The minimal MMTV promoter section  
35 contains a CCAAT box and a TATA element in order to enable efficient

transcription by RNA polymerase II. The cloning and sequencing of the GAL4-MMTV construct took place in analogy to the description of Sambrook J. *et. al.* (Molecular cloning, Cold Spring Harbor Laboratory Press, 1989). Then the complete *Photinus pyralis* gene (Genbank  
5 Accession # M15077) was cloned in 3'-downstream of the GAL4-MMTV element. After sequencing, the luciferase reporter element consisting of five GAL4 binding sites, MMTV promoter and luciferase gene was recloned into a plasmid which confers zeocin resistance in order to obtain the plasmid pΔM-GAL4-Luc-Zeo. This vector was transfected into HEK cells in  
10 accordance with the statements in Ausubel, F.M. *et al.* (Current protocols in molecular biology, Vol. 1-3, John Wiley & Sons, Inc., 1995). Then zeocin-containing medium (0.5 mg/ml) was used to select a suitable stable cell clone that showed very low basal expression of the luciferase gene. In a second step, the PPARα fusion protein (GR-GAL4-  
15 humanPPARα-LBD) was introduced into the stable cell clone described. For this purpose, initially the cDNA coding for the N-terminal 76 amino acids of the glucocorticoid receptor (Genbank Accession # P04150) was linked to the cDNA section coding for amino acids 1-147 of the yeast transcription factor GAL4 (Genbank Accession # P04386). The  
20 cDNA of the ligand-binding domain of the human PPARα receptor (amino acids S167-Y468; Genbank Accession # S74349) was cloned in at the 3'-end of this GR-GAL4 construct. The fusion construct prepared in this way (GR-GAL4-humanPPARα-LBD) was recloned into the plasmid pcDNA3 (from Invitrogen) in order to enable constitutive expression therein  
25 by the cytomegalovirus promoter. This plasmid was linearized with a restriction endonuclease and stably transfected into the previously described cell clone containing the luciferase reporter element. The finished PPARα reporter cell line that contains a luciferase reporter element and constitutively expresses the PPARα fusion protein (GR-  
30 GAL4-human PPARα-LBD) was isolated by selection with zeocin (0.5 mg/ml) and G418 (0.5 mg/ml).

Assay procedure

The activity of PPAR $\alpha$  agonists is determined in a 3-day assay described below:

#### Day 1

- 5 The PPAR $\alpha$  reporter cell line is cultivated to 80% confluence in DMEM (# 41965-039, Invitrogen) which is mixed with the following additions: 10% cs-FCS (fetal calf serum; #SH-30068.03, Hyclone), 0.5 mg/ml zeocin (#R250-01, Invitrogen), 0.5 mg/ml G418 (#10131-027, Invitrogen), 1% penicillin-streptomycin solution (#15140-122, Invitrogen) and 2 mM L-
- 10 glutamine (#25030-024, Invitrogen). The cultivation takes place in standard cell culture bottles (# 353112, Becton Dickinson) in a cell culture incubator at 37°C in the presence of 5% CO<sub>2</sub>. The 80%-confluent cells are washed once with 15 ml of PBS (#14190-094, Invitrogen), treated with 3 ml of trypsin solution (#25300-054, Invitrogen) at 37°C for 2 min, taken up in 5 ml
- 15 of the DMEM described and counted in a cell counter. After dilution to 500.000 cells/ml, 35,000 cells are seeded in each well of a 96 well microtiter plate with a clear plastic base (#3610, Corning Costar). The plates are incubated in the cell culture incubator at 37°C and 5% CO<sub>2</sub> for 24 h.

20

#### Day 2

- PPAR $\alpha$  agonists to be tested are dissolved in DMSO in a concentration of 10 mM. This stock solution is diluted in DMEM (#41965-039, Invitrogen) which is mixed with 5% cs-FCS (#SH-30068.03, Hyclone), 2 mM L-
- 25 glutamine (#25030-024, Invitrogen) and the previously described antibiotics (zeocin, G418, penicillin and streptomycin).

- Test substances are tested in 11 different concentrations in the range from 10  $\mu$ M to 100 pM. More potent compounds are tested in concentration
- 30 ranges from 1  $\mu$ M to 10 pM or between 100 nM and 1 pM.

The medium of the PPAR $\alpha$  reporter cell line seeded on day 1 is completely removed by aspiration, and the test substances diluted in

medium are immediately added to the cells. The dilution and addition of the substances is carried out by a robot (Beckman FX). The final volume of the test substances diluted in medium is 100  $\mu$ l per well of a 96 well microtiter plate. The DMSO concentration in the assay is less than 0.1 % v/v in order to avoid cytotoxic effects of the solvent.

Each plate was charged with a standard PPARalpha agonist, which was likewise diluted in 11 different concentrations, in order to demonstrate the functioning of the assay in each individual plate. The assay plates are incubated in an incubator at 37°C and 5% CO<sub>2</sub> for 24 h.

### Day 3

The PPAR $\alpha$  reporter cells treated with the test substances are removed from the incubator, and the medium is aspirated off. The cells are lysed by pipetting 50  $\mu$ l of Bright Glo reagent (from Promega) into each well of a 96 well microtiter plate. After incubation at room temperature in the dark for 10 minutes, the microtiter plates are measured in the luminometer (Trilux from Wallac). The measuring time for each well of a microtiter plate is 1 sec.

### Evaluation

The raw data from the luminometer are transferred into a Microsoft Excel file. Dose-effect plots and EC<sub>50</sub> values of PPAR agonists are calculated using the XL.Fit program as specified by the manufacturer (IDBS).

The PPARalpha EC<sub>50</sub> values for the compounds of Examples 1 to 85 in this assay are in the range from 0.07nM to >10  $\mu$ M.

The results for the activity of some compounds of the invention of the formula I are indicated in Table I below:

Table 1

- 5 It is evident from Table I that the compounds of the invention of the formula I activate the PPARalpha receptor and thus bring about for example in analogy to fibrates in clinical use a lowering of triglycerides in the body (see, for example, J.-Ch. Fruchard et al.: PPARS, Metabolic Disease and Atherosclerosis, Pharmacological Research, Vol. 44, No. 5, 345-52, 2001;

- 15 (B) Determination of EC50 values of PPAR agonists in the cellular PPARgamma assay

#### Principle

A transient transfection system is employed to determine the cellular

PPARgamma activity of PPAR agonists. It is based on the use of a luciferase reporter plasmid (pGL3basic-5xGAL4-TK) and of a PPARgamma expression plasmid (pcDNA3-GAL4-humanPPARgammaLBD). Both plasmids are transiently transfected into human embryonic kidney cells (HEK cells). There is then expression in these cells of the fusion protein GAL4-humanPPARgammaLBD which binds to the GAL4 binding sites of the reporter plasmid. In the presence of a PPARgamma-active ligand, the activated fusion protein GAL4-humanPPARgammaLBD induces expression of the luciferase reporter gene, which can be detected in the form of a chemiluminescence signal after addition of a luciferase substrate. As a difference from the stably transfected PPARalpha reporter cell line, in the cellular PPAR $\gamma$  assay the two components (luciferase reporter plasmid and PPARgamma expression plasmid) are transiently transfected into HEK cells because stable and permanent expression of the PPARgamma fusion protein is cytotoxic.

#### Construction of the plasmids

The luciferase reporter plasmid pGL3basic-5xGAL4-TK is based on the vector pGL3basic from Promega. The reporter plasmid is prepared by cloning five binding sites of the yeast transcription factor GAL4 (each binding site with the sequence 5'-CTCGGAGGACAGTACTCCG-3' (SEQ ID NO:2)), together with a 160 bp-long thymidine kinase promoter section (Genbank Accession # AF027128) 5'-upstream into pGL3basic. 3'-downstream of the thymidine kinase promoter is the complete luciferase gene from *Photinus pyralis* (Genbank Accession # M15077), which is already a constituent of the plasmid pGL3basic used. The cloning and sequencing of the reporter plasmid pGL3basic-5xGAL4-TK took place in analogy to the description in Sambrook J. *et. al.* (Molecular cloning, Cold Spring Harbor Laboratory Press, 1989).

30

The PPARgamma expression plasmid pcDNA3-GAL4-humanPPAR $\gamma$ LBD was prepared by first cloning the cDNA coding for amino acids 1-147 of the yeast transcription factor GAL4 (Genbank Accession # P04386) into the

plasmid pcDNA3 (from Invitrogen) 3'-downstream of the cytomegalovirus promoter. Subsequently, the cDNA of the ligand-binding domain (LBD) of the human PPAR $\gamma$  receptor (amino acids I152-Y475; Accession # g1480099) 3'-downstream of the GAL4 DNA binding domain. Cloning and  
5 sequencing of the PPARgamma expression plasmid pcDNA3-GAL4-humanPPARgammaLBD again took place in analogy to the description in Sambrook J. *et. al.* (Molecular cloning, Cold Spring Harbor Laboratory Press, 1989). Besides the luciferase reporter plasmid pGL3basic-5xGAL4-TK and the PPAR $\gamma$  expression plasmid pcDNA3-GAL4-  
10 humanPPARgammaLBD, also used for the cellular PPARgamma assay are the reference plasmid pRL-CMV (from Promega) and the plasmid pBluescript SK(+) from Stratagene. All four plasmids were prepared using a plasmid preparation kit from Qiagen, which ensured a plasmid quality with a minimal endotoxin content, before transfection into HEK cells.

15

#### Assay procedure

The activity of PPARgamma agonists is determined in a 4-day assay which is described below. Before the transfection, HEK cells are cultivated in DMEM (# 41965-039, Invitrogen) which is mixed with the following  
20 additions: 10% FCS (#16000-044, Invitrogen), 1% penicillin-streptomycin solution (#15140-122, Invitrogen) and 2 mM L-glutamine (#25030-024, Invitrogen).

#### Day 1

25 Firstly, solution A, a transfection mixture which contains all four plasmids previously described in addition to DMEM, is prepared. The following amounts are used to make up 3 ml of solution A for each 96 well microtiter plate for an assay: 2622  $\mu$ l of antibiotic- and serum-free DMEM (# 41965-039, Invitrogen), 100  $\mu$ l of reference plasmid pRL-CMV (1 ng/ $\mu$ l), 100  $\mu$ l of  
30 luciferase reporter plasmid pGL3basic-5xGAL4-TK (10 ng/ $\mu$ l), 100  $\mu$ l of PPAR $\gamma$  expression plasmid pcDNA3-GAL4-humanPPAR $\gamma$ LBD (100 ng/ $\mu$ l) and 78  $\mu$ l of plasmid pBluescript SK(+) (500 ng/ $\mu$ l). Then 2 ml of solution B are prepared by mixing 1.9 ml of DMEM (# 41965-039, Invitrogen) with 100

$\mu$ l of PolyFect transfection reagent (from Qiagen) for each 96 well microtiter plate. Subsequently, 3 ml of solution A are mixed with 2 ml of solution B to give 5 ml of solution C, which is thoroughly mixed by multiple pipetting and incubated at room temperature for 10 min.

5

80%-confluent HEK cells from a cell culture bottle with a capacity of 175 cm<sup>2</sup> are washed once with 15 ml of PBS (#14190-094, Invitrogen) and treated with 3 ml of trypsin solution (#25300-054, Invitrogen) at 37°C for 2 min. The cells are then taken up in 15 ml of DMEM (# 41965-039,

10 Invitrogen), which is mixed with 10% FCS (# 16000-044, Invitrogen), 1% penicillin-streptomycin solution (#15140-122, Invitrogen) and 2 mM L-glutamine (#25030-024, Invitrogen). After the cell suspension has been counted in a cell counter, the suspension is diluted to 250,000 cells/ml. 15 ml of this cell suspension are mixed with 5 ml of solution C for one  
15 microtiter plate. 200  $\mu$ l of the suspension are seeded in each well of a 96 well microtiter plate with a clear plastic base (#3610, Corning Costar). The plates are incubated in a cell culture incubator at 37°C and 5% CO<sub>2</sub> for 24 h.

20 Day 2

PPAR agonists to be tested are dissolved in DMSO in a concentration of 10 mM. This stock solution is diluted in DMEM (# 41965-039, Invitrogen) which is mixed with 2% Ultrosor (#12039-012, Biosepra), 1% penicillin-streptomycin solution (#15140-122, Invitrogen) and 2 mM L-glutamine  
25 (#25030-024, Invitrogen). Test substances are tested in a total of 11 different concentrations in the range from 10  $\mu$ M to 100 pM. More potent compounds are tested in concentration ranges from 1  $\mu$ M to 10 pM.

The medium of the HEK cells transfected and seeded on day 1 is  
30 completely removed by aspiration, and the test substances diluted in medium are immediately added to the cells. The dilution and addition of the substances is carried out by a robot (Beckman FX). The final volume of the test substances diluted in medium is 100  $\mu$ l per well of a 96 well microtiter

plate. Each plate is charged with a standard PPAR $\gamma$  agonist, which is likewise diluted in 11 different concentrations, in order to demonstrate the functioning of the assay in each individual plate. The assay plates are incubated in an incubator at 37°C and 5% CO<sub>2</sub>.

5

#### Day 4

After removal of the medium by aspiration, 50  $\mu$ l of Dual-Glo™ reagent (Dual-Glo™ Luciferase Assay System; Promega) are added to each well in accordance with the manufacturer's instructions in order to lyse the cells and provide the substrate for the firefly luciferase (Photinus pyralis) formed in the cells. After incubation at room temperature in the dark for 10 minutes, the firefly luciferase-mediated chemiluminescence is measured in a measuring instrument (measuring time/well 1 sec; Trilux from Wallac). Then 50  $\mu$ l of the Dual-Glo™ Stop & Glo reagent (Dual-Glo™ Luciferase Assay System; Promega) is added to each well in order to stop the activity of the firefly luciferase and provide the substrate for the Renilla luciferase expressed by the reference plasmid pRL-CMV. After incubation at room temperature in the dark for a further 10 minutes, a chemiluminescence mediated by the Renilla luciferase is again measured for 1 sec/well in the measuring instrument.

10  
15  
20

#### Evaluation

The crude data from the luminometer are transferred into a Microsoft Excel file. The firefly/Renilla luciferase activity ratio is determined for each measurement derived from one well of the microtiter plate. The dose-effect plots and EC50 values of PPAR agonists are calculated from the ratios by the XL.Fit program as specified by the manufacturer (IDBS).

25

PPAR $\gamma$  EC50 values in the range from 0.08nM to >10  $\mu$ M were measured for the PPAR agonists described in this application.

## Processes

The compounds of the formula I according to the invention can be obtained according to the reaction schemes below:

## 5 Process A:

- The compound A-1 is reacted in an alcohol R-8OH. The resulting product is protected on the secondary hydroxyl group (for example by stirring with TBDPSCI and imidazole in DMF at room temperature), giving the compound A-2, where R8 has the meaning described above. A-2 is, in an ethereal solvent and using lithium aluminum hydride, reduced to give compound A-3. Compound A-3 is reacted in a two-phase system of toluene and 50% strength sodium hydroxide solution at 10°C with tert-butyl bromoacetate and tetrabutylammonium hydrogensulfate to give compound A-4.

Compound A-4 is, in tetrahydrofuran, reacted with lithium diisopropylamide and an alkyl iodide of the formula R6-I, where R6 has the meaning described above. In some examples, the compound obtained in this manner is, in tetrahydrofuran, reacted with lithium diisopropylamide and a  
5 further alkyl iodide of the formula R7-I, where R7 has the meaning described above. The protective group is removed, giving the compound of the formula A-5.

Compound A-5 is, in methyl tert-butyl ether or dimethylformamide, converted into compound A-7 using sodium hydride and the compound A-6  
10 (see process A) where R1, R2, R3 and W have the meanings described above.

The product A-7 is stirred in trifluoroacetic acid or HCl/dioxane for a number of hours. This yields the compound of the formula A-8.

According to this process, it is possible to synthesize examples 31 to 51.  
15

## Process B:

- 5 Compound A-2 where SG = tert-butyldimethylsilyl is, in acetonitrile and at room temperature, converted into compound B-2 using bismuth tribromide, triethylsilane and a compound of the formula B-1 in which R1, R2, W and R3 have the meanings described above.

Using lithium aluminum hydride in diethyl ether or THF, the compound B-2 is reduced to give compound B-3. Compound B-3 is reacted at room temperature with triphenylphosphine and iodine in toluene to give compound B-4.

- 5 Using the compound of the formula B-5 where R6 and R7 have the meanings described above, the compound B-4 is converted into compound B-6. The ester is hydrolyzed by stirring compound B-6 in a mixture of methanol and concentrated aqueous potassium hydroxide solution or lithium hydroxide in THF/methanol/water for a number of hours.
- 10 This gives the compound B-7.

In some examples, the compound B-7 is oxidized at room temperature using one equivalent of hydrogen peroxide in trifluoroacetic acid to give the compound of the formula B-8 in which R1, R2, R3, R6, W and R7 have the meanings described above.

- 15 In some examples, the compound B-7 is oxidized at room temperature with three equivalents of hydrogen peroxide in trifluoroacetic acid to give the compound of the formula B-9 in which R1, R2, R3, R6, W and R7 have the meanings described above.

According to this process, it is possible to synthesize examples 52 to 71.

## Process C:

5 The compound B-3 (see process B) is oxidized at  $-78^\circ\text{C}$  with oxalyl chloride, triethylamine and dimethyl sulfoxide in dichloromethane to give aldehyde C-1. This compound is, using sodium triacetoxyborohydride and the compound of the formula C-2 where R6 and R7 have the meanings described above, converted into compound C-3.

10 Compound C-3 is converted into compound C-4 by stirring in trifluoroacetic acid for a number of hours.

In some examples, the compound C-3 is reacted with acyl chlorides, sulfonyl chlorides or chloroformic esters of the formula  $\text{R9-Cl}$  where R9 has the meaning described above in dichloromethane in the presence of pyridine to give the compound C-5.

By stirring in trifluoroacetic acid for a number of hours, the compound C-5 is converted into compound C-6.

According to this process, it is possible to synthesize examples 72 to 78.

Process D:

The compound D-1 is protected on the hydroxyl group with a suitable protective group, for example with the methoxymethyl protective group. The

carboxyl group is then converted with lithium aluminum hydride in diethyl ether into compound D-2. This compound is reacted with tert-butyl bromoacetate and tetrabutylammonium hydrogensulfate in a two-phase system of toluene/50% strength aqueous sodium hydroxide solution to give compound D-3.

Compound D-3 is deprotected (using, for example, concentrated hydrochloric acid in tetrahydrofuran in the case of the methoxymethyl protective group) and then converted with tert-butyldimethylsilyl chloride and imidazole in dimethylformamide into compound D-4.

- 5 Compound D-4 is deprotonated at 0°C using lithium diisopropylamide in tetrahydrofuran and reacted with an alkyl iodide of the formula R6-I, where R6 has the meaning described above. The resulting compound is then deprotonated at 0°C using lithium diisopropylamide in tetrahydrofuran and reacted with an alkyl iodide of the formula R7-I, where R7 has the meaning  
10 described above, to give the compound D-5.

- Compound D-5 is reacted with bismuth tribromide, triethylsilane and the compound B-1 (see process B) in acetonitrile at room temperature or - after removal of the silyl protective group using TBAF in THF – with potassium tert-butoxide and the compound A-6 (see process A) to give the  
15 compound D-6.

By stirring in trifluoroacetic acid, the compound D-6 is converted into compound D-7.

Using this process, it is possible to synthesize examples 79 and 80.

## Process E:

Using diisobutylaluminum hydride and isopropanol in diethyl ether, the compound E-1 is reduced to give compound E-2. This is reacted with the compound of the formula A-6 and sodium hydride in dimethylformamide to give compound E-3.

Using osmium tetroxide and sodium periodate in diethyl ether, compound E-3 is converted into aldehyde E-4. In a Horner-Emmons-Wadsworth reaction, using a triethyl phosphonoacetate of the formula E-5 in which R6 is as defined above, this compound is converted into compound E-6.

Using hydrogen, the compound E-6 is hydrogenated over palladium/carbon to give compound E-7, and the ester is then hydrolyzed using lithium hydroxide to give the acid E-8.

According to this process, it is possible to synthesize examples 81 to 84.

Process F:

- 5 Using tert-butyldiphenylsilyl chloride and imidazole as base in dimethylformamide, the compound E-2 is reacted, worked up and then reacted with osmium tetroxide and sodium periodate in diethyl ether. The resulting compound is reacted with tert-butyl triphenylphosphoranylideneacetate and n-butyllithium in a Wittig reaction and then hydrogenated with
- 10 hydrogen over palladium/carbon to give compound F-1.

- At 0°C, the compound F-1 is deprotonated using lithium diisopropylamide in tetrahydrofuran and reacted with an alkyl iodide of the formula R6-I, where R6 is as defined above. The resulting compound is then deprotonated using lithium diisopropylamide in tetrahydrofuran at 0°C and reacted with
- 15 an alkyl iodide of the formula R7-I where R7 is as defined above to give the compound F-2.

For deprotection, the compound F-2 is reacted with tetrabutylammonium fluoride in tetrahydrofuran. The resulting alcohol is then reacted with sodium hydride and the compound A-6 in dimethylformamide to give compound F-3.

- 5 The tert-butyl ester is cleaved by stirring compound F-3 for a number of hours in trifluoroacetic acid, giving the compound F-4.

Examples 85 to 92 were synthesized according to this process.

Process G:

10

Using an amino acid ester of the formula G-1 in which  $\text{R}_6$ ,  $\text{R}_7$  and  $\text{R}_8$  are as defined above in the presence of a borohydride reagent (for example sodium triacetoxyborohydride), the compound E-4 is converted into compound G-2.

- 15 Using a chloride  $\text{R}_{12}\text{-Cl}$  in which  $\text{R}_{12}$  is as defined above, compound G-2 is converted into compound G-3 ( $\text{R}_{12}$  may also be isocyanate or isothiocyanate). Compound G-3 is then hydrolyzed with  $\text{LiOH}$  to give compound G-4.

## Process H:

This process is used for the synthesis of building blocks A-6 and B-2 in which R1, R2, W and R3 are as defined above.

5

Using sodium nitrite and hydrochloric acid, the ester H-1 in which R3 is as defined above is converted into oxime H-2 which is reduced by hydrogenation with hydrogen over palladium/carbon to give amine H-3.

- 10 Using acid chlorides of the formula H-4 in which R1, W and R2 are as defined above and base (for example triethylamine), the compound H-3 is converted into compound H-5.

By heating in phosphoryl chloride, the compound H-5 is converted into compound H-6.

The ester H-6 is reduced with lithium aluminum hydride in diethyl ether to give alcohol H-7. This is converted into the iodide A-6 using iodine, imidazole (ImH) and triphenylphosphine.

Alternatively, the compound H-7 is oxidized using oxalyl chloride, dimethyl sulfoxide and triethylamine in dichloromethane at -78°C to give aldehyde B-1.

Process J:

This process is used for synthesizing the building block A-6 in which R1, R2, W and R3 are as defined above.

10

15

In ethanol and using hydrogen chloride, the compound J-1 is reacted with the aldehyde J-2 in which R1, R2, W and R3 are as defined above, to give the compound J-3.

The compound J-3 is heated to the boil in phosphoryl chloride, giving the compound J-4. This is heated to the boil with sodium iodide in acetone. This gives the compound A-6.

15 g of 6-oxabicyclo[3.2.1]octan-7-one are dissolved in 150 ml of methanol, 13 g of sodium methoxide are added and the mixture is stirred at room temperature for 2 h. 13.7 ml of glacial acetic acid are then added, and most of the solvent is distilled off under reduced pressure. The residue is taken up in water and extracted three times with in each case 100 ml of ethyl acetate. The organic phases are dried over  $\text{MgSO}_4$  and then concentrated under reduced pressure. This gives 18.8 g of the methyl ester as a colorless oil. This is dissolved in 150 ml of dichloromethane, 19.2 g of methoxymethyl chloride and 23.2 g of diisopropylethylamine are added and the mixture is stirred at room temperature for 15 h. 250 ml of saturated  $\text{NH}_4\text{Cl}$  solution and 200 ml of water are added to the solution, and the organic phase is separated off. The aqueous phase is extracted with dichloromethane and the combined organic phases are dried over magnesium sulfate and concentrated. This gives 22.2 g of methyl cis-3-(methoxymethoxy)cyclohexanecarboxylate as a yellow oil.  $\text{C}_{10}\text{H}_{18}\text{O}_4$  (202), MS(ESI): 203 ( $\text{MH}^+$ ).

The suspension is stirred at room temperature for 30 min and then cooled to 0°C, and 150 mg of methyl 2-p-tolyloxazol-4-ylmethyl iodide in 1 ml of dimethylformamide are added dropwise. The suspension is stirred at room temperature for 2 h and diluted with methyl tert-butyl ether and saturated NaCl solution. The aqueous phase is removed and extracted with methyl tert-butyl ether. ## tert-Butyl cis-3-(tert-butyldiphenylsilanyloxy)cyclohexylmethoxy]acetate

- 5 25 g of [cis-3-(tert-butyldiphenylsilanyloxy)cyclohexyl]methanol, together with 40 g of tert-butyl bromoacetate and 6.9 g of tetrabutylammonium hydrogensulfate, are dissolved in 300 ml of toluene, and 200 ml of NaOH (50% strength) are then added dropwise at 0°C. The mixture is stirred at 0°C for 1 h and then warmed to room temperature. The solvent is removed and the mixture is extracted with 3 × 100 ml of methyl tert-butyl ether. After the third extraction, the aqueous phase is acidified and once more extracted with 200 ml of methyl tert-butyl ether. The combined organic phases are extracted with saturated sodium chloride solution and dried over magnesium sulfate, and the solvent is removed under reduced pressure. This gives 27.8 g of tert-butyl cis-3-(tert-butyldiphenylsilanyloxy)-cyclohexylmethoxy]acetate as a yellow oil. C<sub>29</sub>H<sub>42</sub>O<sub>4</sub>Si (482.74), MS(ESI): 483 (M+H<sup>+</sup>)

20 tert-Butyl 2-[cis-3-(tert-butyldiphenylsilanyloxy)cyclohexylmethoxy]-2-methylpropionate

- 25 20.0 g of tert-butyl cis-3-(tert-butyldiphenylsilanyloxy)cyclohexylmethoxy]acetate are initially charged in a 1 l three-necked flask, which had been dried by heating, dissolved in 200 ml of dry tetrahydrofuran and cooled to -78°C, and 83 ml of lithium diisopropylamide (2N in tetrahydrofuran) are slowly added dropwise such that the internal temperature does not exceed

-65°C. The mixture is then warmed to 0°C and stirred for 1 h, during which the color of the solution turns to yellow. The mixture is cooled again to -70°C, 35.27 g of methyl iodide are then added dropwise and the mixture is stirred at 0°C for 3 h. The reaction is checked (TLC and LCMS), showing the formation of a new product (monomethyl compound).

200 ml of saturated ammonium chloride solution are added to the reaction mixture, and the mixture is extracted with water/methyl tert-butyl ether. This gives the crude product as a dark-red oil which, without purification, is converted in the same reaction sequence into the geminal dimethyl compound. The crude product is purified on silica gel (heptane/ethyl acetate 50:1 → 10:1). This gives 16 g of tert-butyl 2-[cis-3-(tert-butyl-diphenylsilanyloxy)cyclohexylmethoxy]-2-methylpropionate as a light-yellow oil.

After 2 h of stirring at 60°C, the reaction has ended and the mixture is concentrated under reduced pressure. The residue is extracted from water/ethyl acetate. The combined org. phases are extracted with saturated sodium chloride solution and dried over magnesium sulfate, and the solvent is removed under reduced pressure. The crude product is purified on silica gel (heptane/ethyl acetate 15:1 → 1:1). This gives 16 g of the product tert-butyl 2-(cis-3-hydroxycyclohexylmethoxy)-2-methylpropionate as a colorless oil.

After 15 minutes of stirring at room temperature, 0.12 g of 2-(4-fluorophenyl)-4-iodomethyl-5-methyloxazole is added, and the mixture is stirred at room temperature for 12 h. Following addition of 2 ml of 1N HCl, the product is extracted with ethyl acetate (2 × 5 ml), the solvent is removed under reduced pressure and the crude product is then purified by HPLC. This gives 0.08 g of the compound tert-butyl 2-{cis-3-[2-(4-fluorophenyl)-5-methyloxazol-4-ylmethoxy]cyclohexylmethoxy}-2-methylpropionate as a colorless oil.

1.43 g of KSAc are added to 1.81 g of methyl 2-bromobutyrate in 5ml of dimethylformamide, and the mixture is stirred at room temperature for 12 h. 25 ml of methyl tert-butyl ether, 10 ml of water and 15 ml of saturated NaCl

solution are then added, and the phases are separated. The aqueous phase is extracted with methyl tert-butyl ether and the combined organic phases are washed with saturated NaCl solution, dried over MgSO<sub>4</sub> and concentrated, giving methyl 2-acetylsulfanylbutyrate as a yellow oil. This is taken up in 10 ml of methanol, 11 ml of a 1M NaSMe solution in methanol are added and the mixture is stirred at room temperature overnight. The solvent is distilled off completely under reduced pressure, the residue is taken up in 15 ml of methyl tert-butyl ether and 20 ml of water, the phases are separated and the organic phase is washed with saturated NaCl solution and dried over MgSO<sub>4</sub>. The solution is concentrated under reduced pressure, giving 1.30 g of methyl 2-mercaptobutyrate as a yellow oil.
